Stage Control / Status Bit Map	3-48

CPU Overview

The Central Processing Unit is the heart of the control systems. Almost all system operations are controlled by the CPU, so it is very important to set up and install it correctly. This chapter provides the information needed to understand:

- The differences between the various models of CPUs
- The steps required to setup and install the CPU

General CPU Features

The D4-454 and D4-454DC-1 are modular CPUs which can be installed in, 4, 6, or 8 slot bases. All I/O modules in the DL405 family will work with both of the CPUs. The D4-454 CPUs offer a wide range of processing power and program instructions. Both offer RLL and Stage program instructions (See Chapter 5). Both CPUs have extensive internal diagnostics that can be monitored from the application program or from an operator interface.

CPU Features

The D4-454 has a maximum 30.8K program memory comprised of 15.5K of ladder memory and 15.3K of V-memory (data registers). It supports a maximum of 3584 points of local and local expansion I/O, and 4096 points of remote I/O. It includes an additional internal ARM Cortex M3/4 micro-controller for greater processing power. The D4-454 has 210 instructions, including drum timers, print function, floating point math, trigonometric functions and PID loop control for 16 loops.

The D4-454 has a total of four built-in communication ports. Port 0 has a RS232 interface and supports K Sequence, DirectNET (hex only, Slave only) protocols. Port 1 is RS232/RS422 interface and supports K Sequence, DirectNET, Non-sequence and MODBUS protocols. Port 2 has RS232 interface and supports DirectNET, K-Sequence, Non-sequence, and Modbus RTU protocols. Port 3 is RS422 interface and supports K-Sequence, DirectNet, Non-sequence and MODBUS protocols.

CPU Electrical Specifications

Specification	D4-454	D4-454DC-1
Input Voltage, Nominal	120 or 240 VAC	24 VDC
Input Voltage Range	85-132 VAC and 170-240 VAC	20-29 VDC
Input Voltage Ripple	N/A	< 10%
Inrush Current, maximum	20A	10A
Power Consumption, maximum	50 VA	38W
Voltage Withstand (dielectric strength)	1 minute at 1500 VAC between primary, secondary, field ground and run relay	
Insulation Resistance	> 10MΩ at 500 VDC	
Output Voltage, auxiliary power supply	20-28 VDC (24 nominal), ripple more than 1V P-P	
Output Current, auxiliary power supply	24 VDC @ 400 mA maximum	

CPU Specifications

General Specifications	
Feature	D4-454
Total Program Memory (words)	46.8K
Ladder Memory (words) built-in	31.5K
V-memory (words)	15.3K
Non-volatile V Memory (words)	No
Runtime Edit	Yes
Supports Override	Yes
RLL and RLLPLUS Programming	Yes
Direct SOFT (Programming for Windows)	Yes version 6.1 or later
Built-in Communication Ports	1 RJ12 RS232 1 15-pin RS232 1 25-pin RS232/RS422 1 25-pin RS422
Built-in Memory	Yes (M-RAM)
Number of Instructions Available	210
Control Relays	2048
Special Relays (system defined)	512
Stages in RLLPLUS	1024
V-memory (words)	15360
Timers	256
Counters	256
Immediate I/O	Yes
Interrupt Input	16 points
Subroutines	Yes
Drum Timers	Yes
Table Instructions	Yes
For/Next Loops	Yes
Math	Integer, Floating Point
ASCII	Yes
PID Loop Control, Built -in	Yes, 16 Loops
Time of Day Clock/Calendar	Yes
Internal Diagnostics	Yes
Password Security	Yes, multi-level
System Error Log	Yes
User Error Log	Yes
Battery Backup	D2-BAT-1 included

Local I/O and Local Expansion I/O	
Feature	D4-454
Available Bases	4 (CPU Base, 3 Expansion Bases)
CPU Base Total I/O	512
Local Expansion I/O per Base	512
Total Local I/O and Local Expansion I/O	2048
Local Addressable Discrete Input Points	1024
Local Addressable Discrete Output Points	1024
Local Addressable Analog Input Channels	512
Local Addressable Analog Output Channels	512
Slots per Base	4/6/8
Discrete I/O Module Point Density	8/12/16/32/64

Serial Remote I/O	
Feature	D4-454
Remote I/O Channels	3 (two D4-RM, vvvCPU Port 3)
Total Remote I/O	1536
Remote I/O per Channel	512
Remote I/O Slaves per Channel	7 (share 512 I/O points)
Remote I/O Distance	3300 ft (1000m)
Slots per Base	4/6/8
Discrete I/O Module Point Density	8/12/16/32/64

Ethernet Remote I/O	
Feature	D4-454
Channels per CPU using (H4-ERM100)	Limited by power budget
Slaves per Ethernet Remote Master	16 (H4-EBC)
Total Ethernet Remote I/O points	16384
Total Bases per Slave (H4-EBC)	4 (H4-EBC base, three D4-EX bases)
Slots per Base	4/6/8
Discrete I/O Module Point Density	8/12/16/32/64

Toggle Switch Functions

The CPU mode switch on the D4-454 CPUs provides modes for enabling and disabling program changes in the CPU. Unless the mode switch is in the TERM position, RUN and STOP mode changes will not be allowed by any interface device, DirectSOFT programming software or operator interface. Programs may be viewed or monitored but no changes may be made. If the mode switch is in the TERM position and no program password is in effect, all operating modes as well as program access will be allowed through the connected programming or monitoring device.

Mode Switch	CPU Action
RUN (Run Program)	CPU is forced into the RUN mode if no errors are encountered. No changes are allowed by the attached programming / monitoring device.
TERM (Terminal)	RUN, PROGRAM and Debug modes are available. Mode and program changes are allowed by the programming / monitoring device.
STOP (Stop Program)	CPU is forced into the STOP mode. No changes are allowed by the programming / monitoring device.

Chapter 3: CPU Specifications and Operation

There are two ways to change the CPU mode.

- Use the CPU mode switch to select the operating mode.
- Place the CPU mode switch in the TERM position and use a programming device to change operating modes. In this position, you can change between Run and Program modes.

Status Indicators

The status indicator LEDs on the CPU front panels have specific functions which can help in programming and troubleshooting.

Indicator	Status	Meaning
PWR	ON	Power good
	OFF	Power failure
RUN	ON	CPU is in Run Mode
	OFF	CPU is in Stop or program Mode
	Flashing	CPU is in Firmware Upgrade Mode
CPU	ON	CPU self diagnostics error
	OFF	CPU self diagnostics good
BATT Note: Refer to page 3-8	ON	Low battery voltage (V7745.12 must be On)
	OFF	CPU battery voltage is good or disabled
DIAG	ON	CPU self diagnostics or local bus error
	OFF	CPU self diagnostics and local bus good
I/O	ON	I/O self diagnostics error
	OFF	I/O self diagnostics good
TXD	ON	Data is being transmitted by the CPU
	OFF	No data is being transmitted by the CPU
RXD	ON	Data is being received by the CPU
	OFF	No data is being received by the CPU

Communication Ports

The D4-454 CPUs provide four Serial communication ports.

Port 0 Specifications

The first port is located on the 15-pin D-shell connector. It is for general programming such as DirectSOFT, or operator interface connections. The operating parameters for Port 0 are permanently set to the values shown.

- 15-Pin Female D shell connector
- Protocols: K Sequence, DirectNET (Hex only, Slave only)
- RS232, non isolated, distance with 15m (approx. 50ft)
- 9600 baud, 8 data bits, 1 start, 1 stop bit, Odd parity
- Asynchronous, half-duplex, DTE
- Supports Firmware updates

Port 0 Pin Descriptions		
1	YOP	Sense connection between HPP and CPU
2	TXD	Transmit Data (RS232)
3	RXD	Receive Data (RS232)
4	ON-LINE	Request Communication (TTL)
5	ABNO	CPU error (TTL)
6	PRDY	CPU ready to communicate (TTL)
7	CTS	Clear to Send (RS232)
8	YOM	Sense connection between HPP and CPU
9	-	Not Used
10	LCBL	Sense cable connection (TTL)
11	5V2	5VDC for HPP logic
12	5V2	5VDC for LCD back-light
13	0V	Logic Ground
14	0V	Logic Ground
15	0V	Logic Ground

Port 1 Specifications

Port 1 is located on the 25-pin female D-shell connector. It is for general programming such as DirectSOFT, operator interfaces and networking. Port 1 provides additional features such as programmable baud rate, parity, ASCII/Hex mode and station addresses. Its RS422 signals support multi-drop networking and programming applications.

RS232 or RS422 is selected by cabling to the proper signal pin sets on the connector. Parity, ASCII/Hex mode and station address are selected by using DirectSOFT programming software.

- Protocols: K-Sequence, DirectNet, (master or slave only), Non-Sequence and MODBUS RTU (master or slave)
- RS232 / RS422, selectable address 1-90
- 2400 / 4800 / 9600 / 19200 / 38400 baud (default is 19200)
- 8 data bits, 1 start, 1 stop bit, Odd, Even or No parity (default is 8 data bits, 1 stop bit, Odd parity)
- Asynchronous, half-duplex, DTE
- Supports Firmware updates

Port 1 Pin Descriptions		
1	–	Not Used
2	TXD	Transmit Data (RS232)
3	RXD	Receive Data (RS232)
4	RTS	Ready to Send (RS232)
5	CTS	Clear to Send (RS232)
6	–	Not Used
7	SG	Signal Ground (RS232/RS422)
8	–	(Port 3)
9	RXD+	Receive Data + (RS422)
10	RXD-	Receive Data – (RS422)
11	CTS+	Clear to Send + (RS422)
12	–	(Port 3)
13	–	(Port 3)
14	TXD+	Transmit Data –(RS422)
15	–	Not Used
16	TXD-	Transmit Data–(RS422)
17	–	Not Used
18	RTS-	Request to Send–(RS422)
19	RTS+	Request to Send + (RS422)
20	–	Not Used
21	–	Not Used
22	–	Not Used
23	CTS-	Clear to Send–(RS422)
24	–	(Port 3)
25	–	(Port 3)

Port 2 Specifications

The operating parameters for Port 2 on the D4-454 are configurable using DirectSOFT programming software on a programming device.

- 6-Pin Female modular (RJ12 phone jack) type connector
- Protocols: K-Sequence, DirectNET (master or slave only), Non sequence, Modbus RTU (master or slave)
- RS232, 2400 / 4800 / 9600 (default) / 19200 / 38400 baud
- Nodes (1–90)
- 8 data bits, one start, one stop; Odd, Even, or No parity; (default is 8 data bits, one stop; Odd parity)
- Supports Firmware updates

NOTE: The 5V pins are rated at 200mA maximum, primarily for use with some operator interfaces.

Port 2 Pin Descriptions		
1	0V	Power (–) connection (GND)
2	5V	Power (+) connection
3	RXD	Receive Data (RS232)
4	TXD	Transmit Data (RS232)
5	5V	Power (+) connection
6	0V	Power (–) connection (GND)

Port 3 Specifications

The operating parameters for Port 3 on the D4-454 are configurable using DirectSOFT on a programming device.

- 25 Pin Female modular D type connector
- Protocols: K-Sequence, DirectNET (master or slave) Non-sequence, Modbus RTU (master or slave)
- RS422, selectable address 1-90, 2400 / 4800 / 9600 (default) / 19200 / 38400 baud
- Nodes (1-90)
- 8 data bits (default), one start, one stop (default); Odd (default), Even, or No parity
- Supports Firmware updates

Port 3 Pin Descriptions		
1	–	Not Used
2	–	(port 1)
3	–	(port 1)
4	–	(port 1)
5	–	(port 1)
6	–	Not Used
7	SG	Signal Ground (RS422)
8	–	Not Used
9	–	(port 1)
10	–	(port 1)
11	–	(port 1)
12	TXD+	Transmit Data + (RS422)
13	TXD-	Transmit Data–(RS422)
14	–	(port 1)
15	–	Not Used
16	–	(port 1)
17	–	Not Used
18	–	(port 1)
19	–	(port 1)
20	–	Not Used
21	–	Not Used
22	–	Not Used
23	–	(port 1)
24	RXD+	Receive Data + (RS422)
25	RXD-	Receive Data–(RS422)

A drawing summarizing the pin locations and functions of ports 1 and 3 on the 25-pin connector is to the right. The two logical ports share two ground pins, but have separate communications data pins. When using both logical ports, you will probably have to make a custom connector which divides the signals in two for two separate cables.

Using Battery Backup

A lithium battery is available to maintain the system RAM retentive memory when the system is without external power. Typical CPU battery life is five years, which includes PLC runtime and normal shutdown periods. However, consider installing a fresh battery if your battery has not been changed recently and the system will be shutdown for a period of more than ten days. The battery indicator will flash on and off at 2 Hz when a battery needs changing.

NOTE: Be sure to back up your V-memory and system parameters before replacing your CPU battery. You can do this by using DirectSOFT version 6.1 or later, to save the project, V-memory and system parameters to a personal computer. (File > Save Project). To prevent memory loss, the CPU battery can be changed while the system is powered up. If the CPU has been powered off you should power-up the CPU for at least 5 seconds prior to changing the battery. This ensures the capacitor used to maintain the necessary voltage levels for retaining memory is fully charged.

To install the D2-BAT-1 battery in the CPU:

- Press the retaining clip on the battery door and swing the battery door open (swings downward).
- Place the battery into the coin-type slot with the (+) or larger side out.
- Close the battery door making sure that it locks securely in place.
- Make a note of the date the battery was installed

WARNING: Do not attempt to recharge the battery or dispose of an old battery by fire. The battery may explode or release hazardous materials.

Battery

The battery backup is available immediately after the battery has been installed. The CPU indicator will blink if the battery is low (refer to table on page 3-5). Special Relay 43 (SP43) will also be set when the battery is enabled by setting bit 12 of V7633 (V7633.12). If the low battery feature is not desired, do not set bit V7633.12. The super capacitor will retain memory IF it is configured as retentive regardless of the state of V7633.12. The battery will do the same, but for a much longer time.

CPU Setup Information

Setting the Clock and Calendar

The D4-454 CPUs have a Clock / Calendar that can be used for many purposes. With DirectSOFT programming software you will use the PLC Setup menu options. There are two instructions that allow you change or modify the time and date from within the application program. Chapter 5 provides information on the DATE and TIME instructions that are used to establish the clock and calendar information.

The CPU uses the following format to display the date and time.

- Date—Year, Month, Date, Day of Week (0-6, Sunday through Saturday)
- Time—24 hour format, Hours, Minutes, Seconds

Variable/Fixed Scan Time Feature

The D4-454 CPU offers three types of scan time configurations:

- Variable—this is the standard scan time setting, in which the PLC scan is running as fast as the ladder program execution allows.
- Fixed—the scan time may be set to be constant, from 10ms to 9999ms. The operating system inserts a delay after each ladder scan to accomplish the requested fixed scan.
- Time—The PLC operates with a variable scan, but generates a watchdog timeout error if the scan exceeds the specified amount. You can use this to trap program execution errors, for example.

To select the desired D4-454 scan time option, use DirectSOFT and go online with the D4-454. Then select the PLC > Diagnostics > Scan Time > Setup. The three choices of Variable, Fixed, or Time appear.

Password Protection

The D4-454 CPUs have a password protection function using DirectSOFT. The password must be an eight character numeric (0–9) code. Once you’ve entered a password, you can remove it by entering all zeros (00000000). (This is the default from the factory.)

Multilevel Password The D4-454 CPUs also feature an intermediate level of protection that you can choose by making the first character of the password the character “A”. The remaining seven characters must be numeric (0–9). The intermediate password allows an Operator Interface to communicate with the processor, allowing V memory data changes and does NOT allow edits to the Ladder program.

Clearing an Existing Program

Before entering a new program, it’s a good idea to always clear ladder memory. You can clear an existing program from the CPU and once you are connected using the DirectSOFT programming software go to PLC > Clear Memory.

WARNING: Make sure you remember your password. If you forget your password you will not be able to access the CPU. The CPU must be returned to the factory to have the password (along with the ladder logic project) removed. It is the policy of AutomationDirect to require the memory of the PLC to be cleared along with the password.

Initializing System Memory

The D4-454 CPUs maintain system parameters in a memory area often referred to as the “scratchpad”. In some cases, you may make changes to the system setup that will be stored in system memory. For example, if you specify a range of Control Relays (CRs) as retentive, these changes are stored.

To initialize the “scratchpad”, you need to be connected with the D4-454, go to PLC > Setup > Initialize Scratchpad.

WARNING: You may never have to use this feature unless you want to clear any setup information that is stored in system memory. Usually you’ll only need to initialize the system memory if you are changing programs and the old program required a special system setup. You can usually change from program to program without ever initializing system memory.

Setting Retentive Memory Ranges

The D4-454 CPUs provide certain ranges of retentive memory by default. The default ranges are suitable for many applications, but you can change them if your application requires additional retentive ranges or no retentive ranges at all. The default settings are:

Memory Area	D4-454	
	Default Range	Available Range
Control Relays	C1000 – C3777	C0 – C3777
V-Memory	V400 – V37777	V0 – V37777
Timers	None by default	T0 – T377
Counters	CT0 – CT377	CT0 – CT377
Stages	None by default	S0 – S1777

CPU Operation

Achieving the proper control for your equipment or process requires a good understanding of how D4-454 CPUs control all aspects of system operation. The flow chart shows the main tasks of the CPU operating system. In this section, we will investigate four aspects of CPU operation:

- CPU Operating System—The CPU manages all aspects of system control.
- CPU Operating Modes — The three primary modes of operation are Program Mode, Run Mode, and Debug Mode.
- CPU Timing — The two important areas we discuss are the I/O response time and the CPU scan time.
- CPU Memory Map — The CPUs memory map shows the CPU addresses of various system resources, such as timers, counters, inputs, and outputs.

CPU Operating System

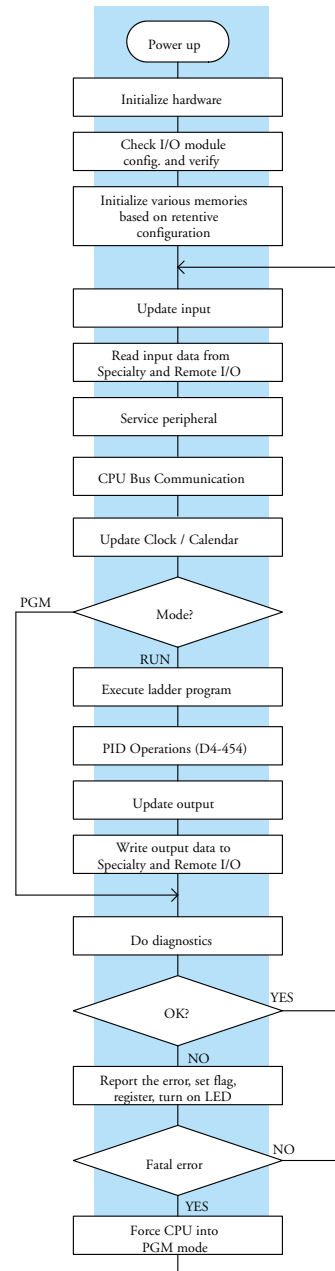

At power up, the CPU initializes the internal electronic hardware. Memory initialization starts with examining the retentive memory settings. In general, the contents of retentive memory are preserved, and non-retentive memory is initialized to zero (unless otherwise specified).

After the one-time power up tasks, the CPU begins the cyclical scan activity. The flowchart to the right shows how the tasks differ, based on the CPU mode and the existence of any errors. The “scan time” is defined as the average time around the task loop. Note that the CPU is always reading the inputs, even during program mode. This allows programming tools to monitor input status at any time.

The outputs are only updated in Run mode. In program mode, they are in the off state.

In Run Mode, the CPU executes the user ladder program. Immediately afterwards, any PID loops which are configured are executed. Then the CPU writes the output results of these two tasks to the appropriate output points.

Error detection has two levels. Non-fatal errors are reported, but the CPU remains in its current mode. If a fatal error occurs, the CPU is forced into program mode and the outputs go off.

Program Mode Operation

In Program Mode the CPU does not execute the application program or update the output modules. The primary use for Program Mode is to enter or change an application program. You also use the program mode to set up CPU parameters, such as the network address, retentive memory areas, etc.

You can use the mode switch on the CPU to select Program Mode operation.

Download Program

Run Mode Operation

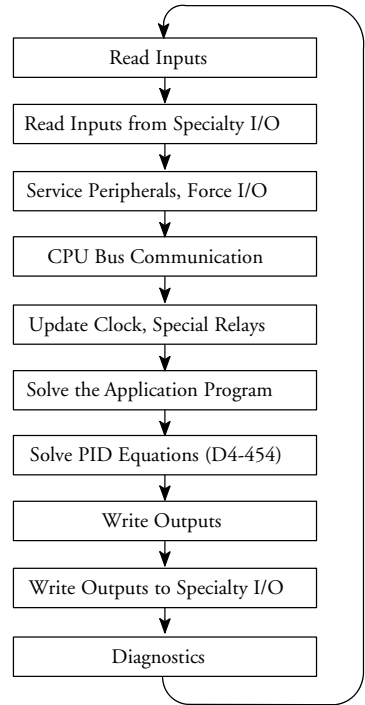

In Run Mode, the CPU executes the application program, does PID calculations for configured PID loops, and updates the I/O system. You can perform many operations during Run Mode. Some of these include:

- Monitor and change I/O point status
- Update timer / counter preset values
- Update Variable memory locations

Run Mode operation can be divided into several key areas. It is very important you understand how each of these areas of execution can affect the results of your application program solutions.

You can use the mode switch to select Run Mode operation.

You can also edit the program during Run Mode. The Run Mode Edits are not “bump-less.” Instead, the CPU maintains the outputs in their last state while it accepts the new program information. If an error is found in the new program, then the CPU will turn all the outputs off and enter the Program Mode.

WARNING: Only authorized personnel fully familiar with all aspects of the application should make changes to the program. Changes during Run Mode become effective immediately. Make sure you thoroughly consider the impact of any changes to minimize the risk of personal injury or damage to equipment.

Read Inputs

The CPU reads the status of all inputs, then stores it in the image register. Input image register locations are designated with an X followed by a memory location. Image register data is used by the CPU when it solves the application program. Of course, an input may change after the CPU has read the inputs. Generally, the CPU scan time is measured in milliseconds. If you have an application that cannot wait until the next I/O update, you can use Immediate Instructions. These do not use the status of the input image register to solve the application program. The Immediate instructions immediately read the input status directly from I/O modules. However, this lengthens the program scan since the CPU has to read the I/O point status again. A complete list of the Immediate instructions is included in Chapter Five.

Read Inputs from Specialty and Remote I/O

After the CPU reads the inputs from the input modules, it reads any input point data from any Specialty modules that are installed, such as High Speed Counter modules, etc. This is also the portion of the scan that reads the input status from Remote I/O bases.

NOTE: *It may appear the Remote I/O point status is updated every scan. This is not quite true. The CPU will receive information from the Remote I/O Master module every scan, but the Remote Master may not have received an update from all the Remote slaves. Remember, the Remote I/O link is managed by the Remote Master, not the CPU.*

Service Peripherals and Force I/O

After the CPU reads the inputs from the input modules, it reads any attached peripheral devices. This is primarily a communications service for any attached devices. For example, it would read a programming device to see if any input, output, or other memory type status needs to be modified. There are two basic types of forcing available with the D4-454 CPUs:

- Forcing from a peripheral – not a permanent force, good only for one scan
- Bit Override – holds the I/O point (or other bit) in the current state. Valid bits are X, Y, C, T, CT, and S. (These memory types are discussed in more detail later in this chapter).

Regular Forcing — This type of forcing can temporarily change the status of a discrete bit. For example, you may want to force an input on, even though it is really off. This allows you to change the point status that was stored in the image register. This value will be valid until the image register location is written to during the next scan. This is primarily useful during testing situations when you need to force a bit on to trigger another event.

Bit Override — Bit override can be enabled on a point-by-point basis by using AUX 59 from the Handheld Programmer or, by a menu option from within DirectSOFT. Bit override basically disables any changes to the discrete point by the CPU. For example, if you enable bit override for X1, and X1 is off at the time, then the CPU will not change the state of X1. This means that even if X1 comes on, the CPU will not acknowledge the change. So, if you used X1 in the program, it would always be evaluated as Off in this case. Of course, if X1 was on when the bit override was enabled, then X1 would always be evaluated as On.

There is an advantage available when you use the bit override feature. The regular forcing is not disabled because the bit override is enabled. For example, if you enabled the Bit Override for Y0 and it was off at the time, then the CPU would not change the state of Y0.

However, you can still use a programming device to change the status. Now, if you use the programming device to force Y0 on, it will remain on and the CPU will not change the state of Y0. If you then force Y0 off, the CPU will maintain Y0 as off. The CPU will never update the point with the results from the application program or from the I/O update until the bit override is removed.

WARNING: Only authorized personnel fully familiar with all aspects of the application should make changes to the program. Changes during Run Mode become effective immediately. Make sure you thoroughly consider the impact of any changes to minimize the risk of personal injury or damage to equipment.

Update Special Relays and Special Registers

There are certain V-memory locations that contain register information. This portion of the execution cycle makes sure these locations get updated on every scan. Also, there are several different Special Relays, such as diagnostic relays, etc., that are also updated during this segment.

CPU Bus Communication

Many of the Specialty Modules, such as the Data Communications Module and the FACTS Co Processor modules, can transfer data to and from the CPU over the CPU bus on the backplane. This data is more than just standard I/O point status. This type of communications can only occur on the CPU (local) base. There is a portion of the execution cycle used to communicate with these modules. The CPU performs both read and write requests during this segment.

Update Clock, Special Relays and Special Registers

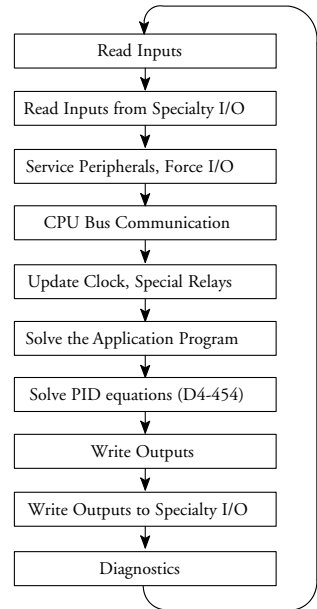

The D4-454 CPUs have an internal real-time clock and calendar timer which is accessible to the application program. Special V-memory locations hold this information. This portion of the execution cycle makes sure these locations get updated on every scan. Also, there are several different Special Relays, such as diagnostic relays, etc., that are also updated during this segment.

Solve Application Program

The CPU evaluates each instruction in the application program during this segment of the scan cycle. The instructions define the relationship between input conditions and the desired output responses.

The CPU begins with the first rung of the ladder program, evaluating it from left to right and from top to bottom. It continues rung by rung until it encounters the END coil instruction. At that point, a new image for the outputs is complete.

The CPU uses the output image register area to store the status of the desired action for the outputs. Output image register locations are designated with a Y followed by a memory location. The actual outputs are updated during the write outputs segment of the scan cycle. There are immediate output instructions available that will update the output points immediately instead of waiting until the write output segment. A complete list of the Immediate instructions is provided in Chapter 5.

The internal control relays (C), the stages (S), the global relays (GY), and the variable memory (V) are also updated in this segment.

You may recall the CPU may have obtained and stored forcing information when it serviced the peripheral devices. If any I/O points or memory data have been forced, the output image register also contains this information.

Solve PID Loop Equations

The D4-454 CPUs can process up to 16 PID loops. The loop calculations are run as a separate task from the ladder program execution, immediately following it. Only loops which have been configured are calculated, and then only according to a built-in loop scheduler. The sample time (calculation interval) of each loop is programmable. Please refer to Chapter 8, PID Loop Operation, for more on the effects of PID loop calculation on the overall CPU scan time.

Write Outputs

Once the application program has solved the instruction logic and constructed the output image register, the CPU writes the contents of the output image register to the corresponding output points located in the local CPU base or the local expansion bases. Remember, the CPU also made sure any forcing operation changes were stored in the output image register, so the forced points get updated with the status specified earlier.

Write Outputs to Specialty and Remote I/O

After the CPU updates the outputs in the local and expansion bases, it sends the output point information that is required by any Specialty modules which are installed. For example, this is the portion of the scan that writes the output status from the image register to the Remote I/O racks

NOTE: It may appear the Remote I/O point status is updated every scan. This is not quite true. The CPU will send the information to the Remote I/O Master module every scan, but the Remote Master will updated the actual remote modules during the next communication sequence between the master and slave modules. Remember, the Remote I/O link communication is managed by the Remote Master, not the CPU.

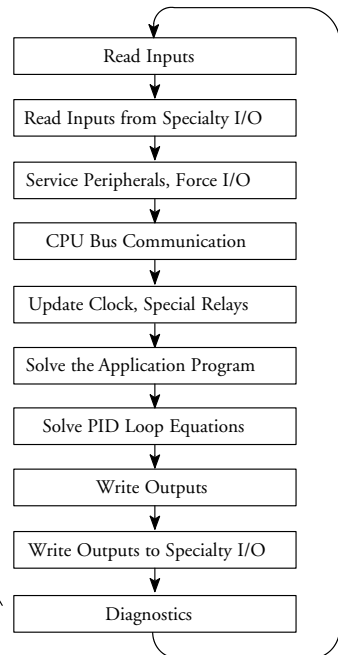

Diagnostics

During this part of the scan, the CPU performs all system diagnostics and other tasks, such as:

- Calculating the scan time
- Updating special relays
- Resetting the watchdog timer

D4-454 CPUs automatically detect and report many different error conditions. Please refer to the Error Codes Appendix which contains a listing of the various error codes available with the DL405 system.

One of the more important diagnostic tasks is the scan time calculation and watchdog timer control. D4-454 CPUs have a “watchdog” timer that stores the maximum time allowed for the CPU to complete the solve application segment of the scan cycle. The default value set from the factory is 200ms. If this time is exceeded the CPU will enter the Program Mode, turn off all outputs, and report the error.

I/O Response Time

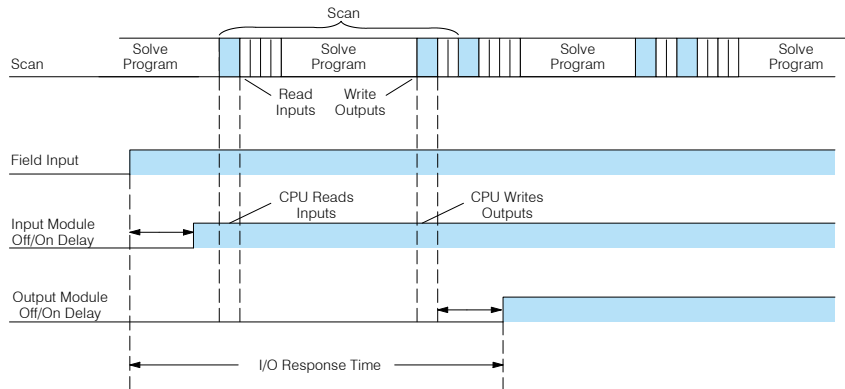

Is Timing Important for Your Application

I/O response time is the amount of time required for the control system to sense a change in an input point and update a corresponding output point. In the majority of applications, the CPU performs this task practically instantaneously. However, some applications do require extremely fast update times. There are four things that can affect the I/O response time.

- The point in the scan period when the field input changes states
- Input module Off to On delay time
- CPU scan time
- Output module Off to On delay time

Normal Minimum I/O Response

The I/O response time is shortest when the module senses the input change just before the Read Inputs portion of the execution cycle. In this case the input status is read, the application program is solved, and the output point gets updated. The following diagram shows an example of the timing for this situation.

In this case, you can calculate the response time by simply adding the following items:

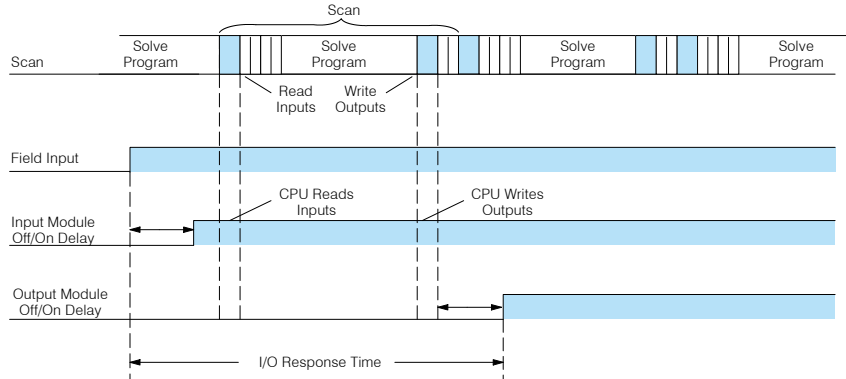

$$\text{Input Delay} + \text{Scan Time} + \text{Output Delay} = \text{Response Time}$$

Normal Minimum I/O Response

The I/O response time is longest when the modules senses the input change just after the Read Inputs portion of the execution cycle. In this case the new input status does not get read until the following scan. The following diagram shows an example of the timing for this situation.

In this case, you can calculate the response time by simply adding the following items.

$$\text{Input Delay} + (2 \times \text{Scan Time}) + \text{Output Delay} = \text{Response Time}$$

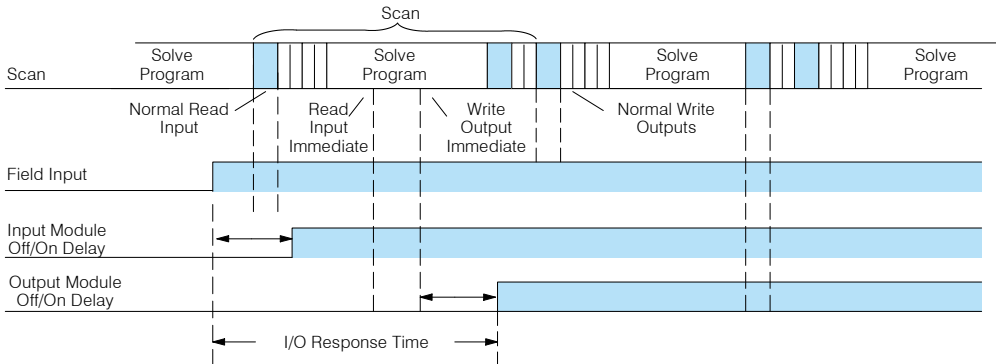

Improving Response Time

There are a few things you can do to help improve throughput.

- Choose instructions with faster execution times
- Use immediate I/O instructions (which update the I/O points during the ladder program execution segment)
- Choose modules that have faster response times

Immediate I/O instructions are probably the most useful technique. The following example shows immediate input and output instructions, and their effect.

In this case, you can calculate the response time by simply adding the following items.

$$\text{Input Delay} + \text{Instruction Execution Time} + \text{Output Delay} = \text{Response Time}$$

The instruction execution time is calculated by adding the time for the immediate input instruction, the immediate output instruction, and all instructions in between.

NOTE: When the immediate instruction reads the current status from a module, it uses the results to solve that one instruction without updating the image register. Therefore, any regular instructions that follow will still use image register values. Any immediate instructions that follow will access the module again to update the status.

CPU Scan Time Considerations

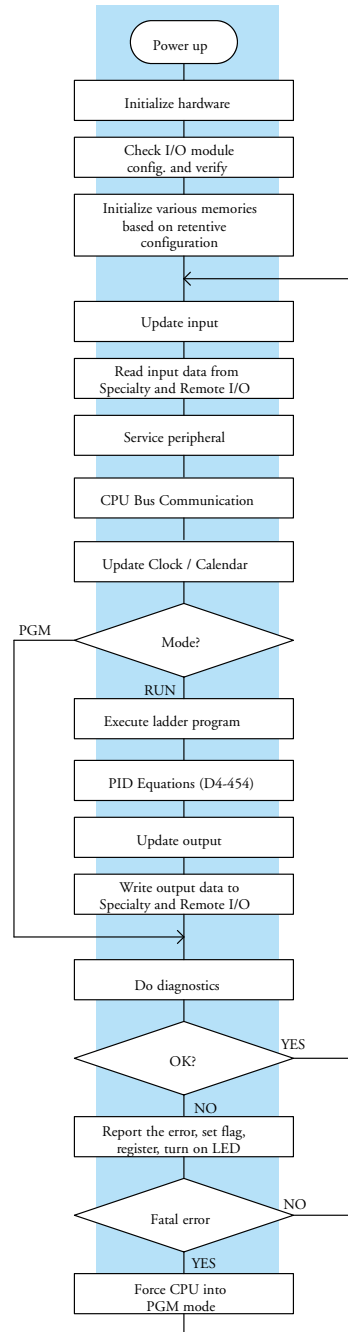

The scan time covers all the cyclical tasks that are performed by the operating system. You can use DirectSOFT to display the minimum, maximum, and current scan times that have occurred since the previous Program Mode to Run Mode transition. This information can be very important when evaluating the performance of a system.

As we've shown previously there are several segments that make up the scan cycle. Each of these segments require a certain amount of time to complete. Of all the segments, the only one you really have the most control over is the amount of time it takes to execute the application program. This is because different instructions take different amounts of time to execute. So, if you think you need a faster scan, then you can try to choose faster instructions.

Your choice of I/O modules and system configuration, such as expansion or remote I/O, can also affect the scan time. However, these things are usually dictated by the application.

For example, if you have a need to count pulses at high rates of speed, then you'll probably have to use a High-Speed Counter module. Also, if you have I/O points that need to be located several hundred feet from the CPU, then you need remote I/O because it's much faster and cheaper to install a single remote I/O cable than it is to run all those wires for each individual I/O point.

The following paragraphs provide some of the general information on how much time some of the segments can require.

Initialization Process

The CPU performs an initialization task once the system power is on. The required time depends on system loading, such as the number of I/O modules installed. The initialization task is performed once at power-up, so it does not affect the scan time for the application program.

Initialization	
Minimum Time	1.9 Seconds
Maximum Time	3.3 Seconds

Reading Inputs

The time required to read the input status for the local and expansion input modules depends on the number of input points in the bases, and the number of input modules being used. The following table shows typical update times.

Timing Factors	
Overhead	20.0 μ s
Per input modules	13.0 μ s
Per input point	6.3 μ s

Update Clock/Calendar, Special Relays, Special Registers

For example, the time required for a D4-454 to read two 16-point input modules would be calculated as follows (Where NM is the number of modules and NI is the total number of input points.)

- Formula
- $\text{Time} = 20 \mu\text{s} + (13 \mu\text{s} \times \text{NM}) + (6.3 \mu\text{s} \times \text{NI})$

Example

- $\text{Time} = 20 \mu\text{s} + (13 \mu\text{s} \times 2) + (6.3 \mu\text{s} \times 16)$
- $\text{Time} = 146.8 \mu\text{s}$

NOTE: This information provides the amount of time the CPU spends reading the input status from the modules. Don't confuse this with the I/O response time that was discussed earlier.

Reading Inputs from Specialty I/O

During this portion of the cycle the CPU reads any input points associated with the following:

- Remote I/O
- Specialty Modules (such as High-Speed Counter, etc.)

The time required to read any input status from these modules depends on the number of modules and the number of input points.

For example, the time required for D4-454 to read two 32-point input modules (located in a Remote base) and the input points associated with a single High-Speed Counter module would be calculated as follows. (Where NM is the number of modules and NI is the number of input points in a module.)

Specialty Module	
Overhead	20.0 μ s
Per Module (with inputs)	13.0 μ s
Per input point	13.8 μ s

Remote Module	
Overhead	19.0 μ s
Per Module (with inputs)	62.0 μ s
Per input point	11.2 μ s

Remote I/O

- Formula
- Time = $19 \mu\text{s} + (62 \mu\text{s} \times \text{NM}) + (11.2 \mu\text{s} \times \text{NI})$

Example

- Time = $19\mu\text{s} + (62 \mu\text{s} \times 2) + (11.2 \mu\text{s} \times 32)$
- Time = 501.4 μ s

High Speed Counter

- Formula
- Time = $20 \mu\text{s} + (13 \mu\text{s} \times \text{NM}) + (13.8 \mu\text{s} \times \text{NI})$

Example

- Time = $20 \mu\text{s} + (13 \mu\text{s} \times 2) + (13.8 \mu\text{s} \times 16)$
- Time = 266.8 μ s

$$\text{Total Time} = 501.4 \mu\text{s} + 266.8 \mu\text{s} = 768.2 \mu\text{s}$$

Service Peripherals

Communication request can occur at any time during the scan, but the CPU only “logs” the requests for service until the Service Peripherals portion of the scan. (The CPU does not spend any time on this if there are no peripherals connected.)

To Log Request (anytime)	D4-454	
Nothing Connected	Min. & Max.	0 μ s
Port 0	Send Min. / Max.	38 / 38 μ s
	Rec. Min. / Max.	45 / 45 μ s
Port 1	Send Min. / Max.	41 / 48 μ s
	Rec. Min. / Max.	47 / 59 μ s
Port 2	Send Min. / Max.	41 / 48 μ s
	Rec. Min. / Max.	47 / 59 μ s
Port 3	Send Min. / Max.	38 / 38 μ s
	Rec. Min. / Max.	45 / 45 μ s

To Service Request	D4-454
Minimum	96 μ s
Run Mode Max.	160 ms
Program Mode Max.	11.2 Second

During the Service Peripherals portion of the scan, the CPU analyzes the communications request and responds as appropriate. The amount of time required to service the peripherals depends on the content of the request.

CPU Bus Communications

Some specialty modules can also communicate directly with the CPU via the CPU Bus. During this portion of the cycle the CPU completes any CPU Bus Communications. The actual time required depends on the type of modules installed and the type of request being processed.

NOTE: Some specialty modules can have a considerable impact on the CPU scan time. If timing is critical in your application, consult the module documentation for any information concerning the impact on the scan time.

Update Clock/Calendar, Special Relays, Special Registers

The clock, calendar, and special relays are updated and loaded into special V-memory locations during this time. This update is performed during both RUN and Program modes.

Modes		D4-454
Program Mode	Minimum	12.0 μ s
	Maximum	12.0 μ s
Run Mode	Minimum	22.0 μ s
	Maximum	29.0 μ s

Writing Outputs

The time required to write the output status for the local and expansion I/O modules depends on the number of output points that are in these bases and the number of output modules being used. The following table shows typical update times required by the CPU.

Timing Factors	D4-454
Overhead	15.0 μ s
Per output module	13.0 μ s
Per output point	14.1 μ s

For example, the time required for a D4-454 to write data for two 32-point output modules would be calculated as follows (where NM is the number of modules and NO is the number of output points in a module).

- Formula
- $\text{Time} = 15\mu\text{s} + (13\mu\text{s} \times \text{NM}) + (14.1\mu\text{s} \times \text{NI})$

Example

- $\text{Time} = 15\mu\text{s} + (13\mu\text{s} \times 2) + (14.1\mu\text{s} \times 32)$
- $\text{Time} = 492.2\mu\text{s}$

Writing Outputs to Specialty I/O

During this portion of the cycle the CPU writes any output points associated with the following:

- Remote I/O
- Specialty Modules (such as High-Speed Counter, etc.)

The time required to write any output image register data to these modules depends on the number of modules and the number of output points.

Specialty Modules	D4-454
Overhead	18.0 μ s
Per module (with outputs)	13.0 μ s
Per output point	14.1 μ s
Remote Modules	D4-454
Overhead	15.0 μ s
Per module (with outputs)	54.0 μ s
Per output point	13.9 μ s

For example, the time required for D4-454 to write two 32-point output modules (located in a Remote base) and the output points associated with a single High-Speed Counter module would be calculated as follows. (Where NM is the number of modules and NI is the number of output points in a module.)

Remote I/O

- Formula
- Time = $15\mu\text{s} + (54\mu\text{s} \times \text{NM}) + (13.9 \mu\text{s} \times \text{NI})$

Example

- Time = $15\mu\text{s} + (54\mu\text{s} \times 2) + (13.9 \mu\text{s} \times 32)$
- Time = 567.8 μ s

High Speed Counter

- Formula
- Time = $18\mu\text{s} + (13\mu\text{s} \times \text{NM}) + (14.1 \mu\text{s} \times \text{NI})$

Example

- Time = $18\mu\text{s} + (13\mu\text{s} \times 2) + (14.1 \mu\text{s} \times 16)$
- Time = 269.6 μ s

NOTE: The total time is the actual time required for the CPU to update these outputs. This does not include any additional time that is required for the CPU to actually service the particular specialty modules.

Diagnostics

The D4-454 CPU performs many types of system diagnostics. The amount of time required depends on many things, such as the number of I/O modules installed, etc. The following table shows the minimum and maximum times that can be expected.

Diagnostic Time	D4-454
Minimum	282.0 μ s
Maximum	398.0 μ s

Application Program Execution

The CPU processes the program from the top (address 0) to the END instruction. The CPU executes the program left to right and top to bottom. As each rung is evaluated the appropriate image register or memory location is updated.

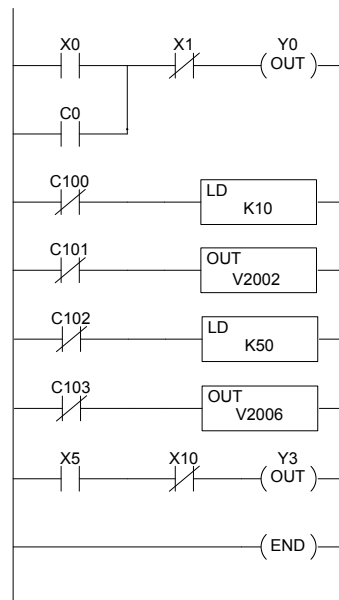

The time required to solve the application program depends on the type and number of instructions used, and the amount of execution overhead.

You can add the execution times for all the instructions in your program to find the total program execution time.

For example, the execution time for a D4-454 running the program shown would be calculated as follows.

Program Control Instructions

Instruction	Time
STR X0	0.96 μ s
OR C0	0.9 μ s
ANDN X1	0.9 μ s
OUT Y0	2.9 μ s
STRN C100	1.0 μ s
LD K10	12.7 μ s
STRN C101	1.0 μ s
OUT V2002	4.7 μ s
STRN C102	1.0 μ s
LD K50	12.7 μ s
STRN C103	1.0 μ s
OUT V2006	4.7 μ s
STR X5	4.7 μ s
ANDN X10	0.9 μ s
OUT Y3	2.9 μ s
END	8.5 μ s
TOTAL	61.6 μs

The D4-454 offers additional instructions that can change the way the program executes. These instructions include FOR/NEXT loops, Subroutines and Interrupt Routines. These instructions can interrupt the normal program flow and affect the program execution time. Chapter 5 provides detailed information on how these different types of instructions operate.

PLC Numbering Systems

If you are a new PLC user or are using AutomationDirect PLCs for the first time please take a moment to study how our PLCs use numbers. You'll find that each PLC manufacturer has their own conventions on the use of numbers in their PLCs. We want to take just a moment to familiarize you with how numbers are used in the DirectLOGIC PLCs. As any good computer does, PLCs store and manipulate numbers in binary form: just ones and zeros. So why do we have to deal with numbers in so many different forms? Numbers have meaning, and some representation are more convenient than others for particular purposes. Sometimes we use numbers to represent a size or amount of something. Other numbers refer to locations or addresses, or to time. In science we attach engineering units to numbers to give a particular meaning. (See the Number Systems Appendix for numbering system details.)

octal	49.832	binary
? 1482	BCD ?	? 0402 ?
3A9	7 -961428	ASCII
1001011011	hexadecimal	
decimal	177 ?	1011
-300124	A	72B ?

PLC Resources

PLCs offer a fixed amount of resources, depending on the model and configuration. We use the word "resources" to include variable memory (V-memory), I/O points, timers, counters, etc. Most modular PLCs allow you to add I/O points in groups of eight. In fact, all the resources of our DirectLOGIC are counted in octal. It's easier for computers to count in groups of eight than ten, because eight is an even power of 2.

Octal means simply counting in groups of eight things at a time. In the figure to the right, there are eight circles. The quantity in decimal is "8", but in octal it is "10" (8 and 9 are not valid in octal). In octal, "10" means 1 group of 8 plus 0 (no individuals).

After counting PLC resources, it's time to access PLC resources (there's a difference). The CPU instruction set accesses resources of the PLC using octal addresses. Octal addresses are the same as octal quantities, except they start counting at zero. The number zero is significant to a computer, so we don't skip it.

Our circles are in an array of square containers to the right. To access a resource, our PLC instruction will address its location using the octal references shown. If these were counters, "CT14" would access the black circle location.

V-Memory

Variable memory (V-memory) stores data for the ladder program and for configuration settings. V-memory locations and V-memory addresses are the same thing, and are numbered in octal. For example, V2073 is a valid location, while V1983 is not valid (“9” and “8” are not valid octal digits).

Each V-memory location is one data word wide, meaning 16 bits. For configuration registers, our manuals will show each bit of a V-memory word. The least significant bit (LSB) will be on the right and the most significant bit (MSB) on the left. We use the word “significant”, referring to the relative binary weighting of the bits.

V-memory is 16-bit binary, but we rarely program the data registers one bit at a

time. We use instructions or viewing tools that let us work with binary, decimal, octal and hexadecimal numbers. All these are converted and stored as binary for us.

A frequently-asked question is “How do I tell if a number is binary, octal, BCD, or hex”? The answer is that we usually cannot tell just by looking at the data, but it does not really matter. What matters is: the source or mechanism which writes data into a V-memory location and the thing which later reads it must both use the same data type (i.e., octal, hex, binary, or whatever). The V-memory location is just a storage box, that’s all. It does not convert or move the data on its own.

Binary-Coded Decimal Numbers

Since humans naturally count in decimal (10 fingers, 10 toes), we prefer to enter and view PLC data in decimal as well (via operator interfaces). However, computers are more efficient in using pure binary numbers. A compromise solution between the two is Binary-Coded Decimal (BCD) representation. A BCD digit ranges from 0 to 9, and is stored as four binary bits (a nibble). This permits each V-memory location to store four BCD digits, with a range of decimal numbers from 0000 to 9999.

In a pure binary sense, a 16-bit word represents numbers from 0 to 65535. In storing BCD numbers, the range is reduced to 0 to 9999. Many math instructions use BCD data, and DirectSOFT allows us to enter and view data in BCD. Special RLL instructions convert from BCD to binary, or visa-versa.

Hexadecimal Numbers

Hexadecimal numbers are similar to BCD numbers, except they utilize all possible binary values in each 4-bit digit. They are base-16 numbers so we need 16 different digits. To extend our decimal digits 0 through 9, we use A through F as shown.

A 4-digit hexadecimal number can represent all 65536 values in a V-memory word.

Decimal	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Hexadecimal	0	1	2	3	4	5	6	7	8	9	A	B	C	D	E	F

The range is from 0000 to FFFF (hex). PLCs often need this full range for sensor data, etc. Hexadecimal is just a convenient way for humans to view full binary data.

Memory Map

With any PLC system, you generally have many different types of information to process. This includes input device status, output device status, various timing elements, part counts, etc. It is important to understand how the system represents and stores the various types of data. For example, you need to know how the system identifies input points, output points, data words, etc. The following paragraphs discuss the various memory types used in the D4-454 CPUs. Memory maps follow the memory descriptions.

Octal Numbering Systems

All memory locations or areas are numbered in octal (base 8). The diagram shows how the octal numbering system works for the discrete input points. Notice the octal system does not contain any numbers with the digits 8 or 9.

Refer to the previous section on PLC Numbering Systems for more on octal numbering.

Discrete and Word Locations

As you examine the different memory types, you'll notice two types of memory in the DL405, discrete and word memory. Discrete memory is one bit that can be either a 1 or a 0. Word memory is referred to as V-memory (variable) and is a 16-bit location normally used to manipulate data/numbers, etc.

Some information is automatically stored in V-memory. For example, the timer current values are stored in V-memory.

Discrete – On or Off, 1 bit

V-Memory Locations for Discrete Memory Areas

The discrete memory area is for inputs, outputs, control relays, special relays, stages, global relays, timer status bits and counter status bits. However, you can also access the bit data types as V-memory word. Each V-memory location contains 16 consecutive discrete locations. For example, the following diagram shows how the X inputs are mapped into V-memory locations.

Word Locations – 16 bits

These discrete memory areas and the corresponding V-memory locations are listed in the Memory Map tables for the D4-454 in this chapter.

16 Discrete (X) Input Points

Input Points (X Data Type)

The discrete input points are noted by an X data type. Refer to the memory maps for the number of discrete input points for your CPU. In this example the output point Y0 will energize when input X0 turns on.

Output Points (Y Data Type)

The discrete output points are noted by a Y data type. Refer to the memory maps for the number of discrete input points for your CPU. In this example, output point Y1 will energize when input X1 turns on.

Control Relays (C Data Type)

Control relays are discrete bits normally used to control the user program. The control relays do not represent a real world device, that is, they cannot be physically tied to switches, output coils, etc. They are internal to the CPU. Because of this, control relays can be programmed as discrete inputs or discrete outputs. These locations are used in programming the discrete memory locations (C) or the corresponding word location which contains 16 consecutive discrete locations.

In this example, memory location C5 will energize when input X6 turns on. The second rung shows a simple example of how to use a control relay as an input.

Timers and Timer Status Bits (T Data Type)

Regardless of the number of timers, you have access to timer status bits that reflect the relationship between the current value and the preset value of a specified timer. The timer status bits will be on when the current value is equal or greater than the preset value of a corresponding timer.

In this example, when input X0 turns on, timer T1 will start. When the timer reaches the preset of 3 seconds (K of 30) timer status contact T1 turns on. When T1 turns on, output Y12 turns on. Turning off X0 resets the timer.

NOTE: Some timers and counters use one V-memory register, and other types require two V-memory registers. See the instruction descriptions in Chapter 5.

Timer Current Values (V Data Type)

Some information is automatically stored in V-memory, such as the current values associated with timers. For example V0 holds the current value for Timer 0, V1 holds the current value for Timer 1, etc. These are 4-digit BCD values.

The primary reason for this is programming flexibility. The example shows you how you can use relational contacts to monitor several time intervals from a single timer.

Counters and Counter Status Bits (CT Data type)

There are 128 counters available in the CPU. Counter status bits that reflect the relationship between the current value and the preset value of a specified counter. The counter status bit will be on when the current value is equal to or greater than the preset value of a corresponding counter.

Each time contact X0 transitions from off to on, the counter increments by one. (If X1 comes on, the counter is reset to zero.) When the counter reaches the preset of 10 counts (K of 10) counter status contact CT3 turns on. When CT3 turns on, output Y2 turns on.

Counter Current Values (V Data Type)

Just like the timers, the counter current values are also automatically stored in V-memory. For example, V1000 holds the current value for Counter CT0, V1001 holds the current value for Counter CT1, etc. These can also be designated as CTA0 (Counter Accumulated) for Counter 0 and CTA01 for Counter 1.

The primary reason for this is programming flexibility. The example shows how you can use relational contacts to monitor the counter values.

Word Memory (V Data Type)

Word memory is referred to as V-memory (variable) and is a 16-bit location normally used to manipulate data/numbers, store data/numbers, etc.

Some information is automatically stored in V-memory. For example, the timer current values are stored in V-memory.

The example shows how a four-digit BCD constant is loaded into the accumulator and then stored in a V-memory location.

Stages (S Data type)

Stages are used in RLLPLUS programs to create a structured program, similar to a flowchart. Each program Stage denotes a program segment. When the program segment, or Stage, is active, the logic within that segment is executed. If the Stage is off, or inactive, the logic is not executed and the CPU skips to the next active Stage. (See Chapter 7 for a more detailed description of RLLPLUS programming.)

Each Stage also has a discrete status bit that can be used as an input to indicate whether the Stage is active or inactive. If the Stage is active, then the status bit is on. If the Stage is inactive, then the status bit is off. This status bit can also be turned on or off by other instructions, such as the SET or RESET instructions. This allows you to easily control stages throughout the program.

Special Relays (SP Data Type)

Special relays are discrete memory locations with pre-defined functionality. There are many different types of special relays. For example, some aid in program development, others provide system operating status information, etc. Please see the Special Relays Appendix for a complete listing of the special relays.

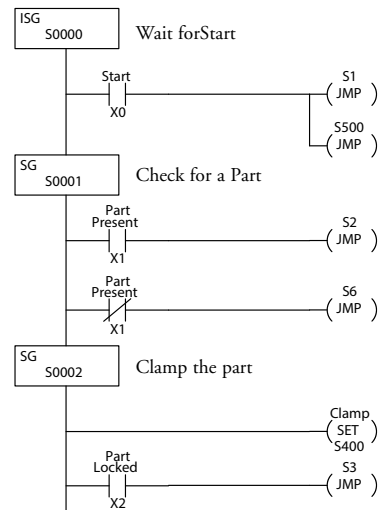

In this example, control relay C10 will energize for 50ms and de-energize for 50ms because SP5 is a pre-defined relay that will be on for 50ms and off for 50ms.

Remote I/O Points (GX and GY Data Type)

Remote I/O points are represented by global relays. They are generally used only to control remote I/O, but they can be used as normal control relays when remote I/O is not used in the system. There are setup routines that must be placed in your application program to designate which locations are inputs and which are outputs. (The DL405 Remote and Slice I/O modules manual provides the details.)

In this example, memory location GY0 turns on when local input X3 is not ON. On the second rung, local output Y12 will turn ON when GX10 turns on.

Ladder Representation

SP4: 1 second clock
 SP5: 100 ms clock
 SP6: 50 ms clock

System Parameters (V Data Type)

Many system parameters, such as error codes, are automatically stored in pre-defined V-memory locations. These memory locations store clock / calendar information, error codes and other types of system setup information.

System V-Memory	Description of Contents
V737	Contains a BCD value (from 3 to 999) for Timed-interrupt 17 feature.
V7633	Bit 12 enables the low battery warning indicator.
V7747	Contains a 10 mS calendar timer used with the Clock / Calendar
V7766	Contains the number of seconds on the clock. (00 to 59)
V7767	Contains the number of minutes on the clock. (00 to 59)
V7770	Contains the number of hours on the clock. (00 to 23)
V7771	Contains the day of the week. (0=Sun., 1=Mon, etc.)
V7772	Contains the day of the month (1st, 2nd, etc.)
V7773	Contains the month. (01 to 12)
V7774	Contains the year. (00 to 99)

System V-Memory	Description of Contents
V736	Contains a BCD value (from 3 to 999) for Timed-interrupt 16 feature.
V7746	454: Battery voltage in tenths of a volt, (e.g., V7746 = 0031 is 3.1 Volts)

System V-Memory (continued)	Description of Contents
V7751	Fault Message Error Code — stores the 4-digit BCD code used with the FAULT instruction when the instruction is executed. If you've used ASCII messages, then the data label (DLBL)reference number for that message is stored here.
V7752	I/O configuration Error — stores the module ID code for the module that does not match the current configuration.
V7753	I/O Configuration Error — stores the correct module ID code.
V7754	I/O Configuration Error — identifies the base and slot number.
V7755	Error code — stores the fatal error code.
V7756	Error code — stores the major error code.
V7757	Communications Error Code — stores the minor error code.
V7760	Module Error — identifies the base and slot number.
V7762	Module Error — identifies the type of error.
V7763	Program Grammatical Error — identifies the location of a syntax error in a program.
V7764	Program Grammatical Error — identifies the type of error.
V7765	Scan — stores the total number of scan cycles that have occurred since the last Program Mode to Run Mode transition.
V7775	Scan — stores the current scan time.
V7776	Scan — stores the minimum scan time that has occurred since the last Program-to-Run Mode transition.
V7777	Scan — stores the maximum scan time that has occurred since the last Program-to-Run Mode transition.

Systems CRs	Description of Contents
C740	Completion of setups: Ladder logic must turn this relay on when it has finished writing to the Remote I/O setup table.
C741	ON: The last state of inputs will be maintained OFF: The inputs will turn off when communication is lost
C743	Re-Start: Turning on this relay will resume after a communication hang-up on an error
C750 to C757	Setup Error: The corresponding relay will be ON if the setup table contains an error (C7250 = master, C751 =slave 1 C757 = slave 7)
C760 to C767	Communication Ready: The corresponding relay will be ON if the setup table data is valid (C760 = master, C761 = slave 1, C767 = slave 7)

Memory Type	Discrete Memory Reference (octal)	Word Memory Reference (octal)	Qty. Decimal	Symbol
Input Points	X0 – X1777	V40400 – V40477	1024	
Output Points	Y0 – Y1777	V40500 – V40577	1024	
Control Relays	C0 – C3777	V40600 – V40777	2048	
Special Relays	SP0 – SP777	V41200 – V41237	512	
Timers	T0 – T377	V41100 – V41117	256	
Timer Current Values	None	V00000 – V00377	256	
Timer Status Bits	T0 – T377	V41100 – V41117	256	
Counters	CT0 – CT377	V41140 – V41157	256	
Counter Current Values	None	V01000 – V01377	256	
Counter Status Bits	CT0 – CT377	V41140 – V41157	256	
User Data Types	None	V1400 – V7377 V10000 – V36777	3072 11776	None specific, use with many instructions
Stages	S0 – S1777	V41000 – V41077	1024	
Remote In / Out	GX0 – GX3777 GY0 – GY3777	V40000 – V40177 V40200 – V40377	2048 2048	
System Parameters	None	V700 – V777 V7400 – V7777 V37000 – V37777	832	None specific, use with many instructions

DL405 Aliases

An alias is an alternate way of referring to certain memory types, such as timer / counter current values, V-memory locations for I/O points, etc., which simplifies understanding the memory address. The use of alias is optional, but some users may find the alias to be helpful when developing a program. The table below shows how the aliases can be used to reference memory locations.

Address Start	Alias Start	Example
V0	TA0	V0 is the timer accumulator value for timer 0, therefore, its alias is TA0. TA1 is the alias for V1, etc.
V1000	CTA0	V1000 is the counter accumulator value for counter 0, therefore, it's alias is CTA0. CTA1 is the alias for V1001, etc.
V40000	VGX	V40000 is the word memory reference for discrete bits GX0 through GX17, therefore, it's alias is VGX0. V40001 is the word memory reference for discrete bits GX20 through GX 37, therefore, its alias is VGX20.
V40200	VGX	V40200 is the word memory reference for discrete bits GY0 through GY17, therefore, it's alias is VGY0. V40201 is the word memory reference for discrete bits GY20 through GY 37, therefore, it's alias is VGY20.
V40400	VX0	V40400 is the word memory reference for discrete bits X0 through X17, therefore, it's alias is VX0. V40401 is the word memory reference for discrete bits X20 through X37, therefore, its alias is VX20.
V40500	VY0	V40500 is the word memory reference for discrete bits Y0 through Y17, therefore, it's alias is VY0. V40501 is the word memory reference for discrete bits Y20 through Y37, therefore, its alias is VY20.
V40600	VC0	V40600 is the word memory reference for discrete bits C0 through C17, therefore, it's alias is VC0. V40601 is the word memory reference for discrete bits C20 through C37, therefore, its alias is VC20.
V41000	VS0	V41000 is the word memory reference for discrete bits S0 through S17, therefore, it's alias is VS0. V41001 is the word memory reference for discrete bits S20 through S37, therefore, its alias is VS20.
V41100	VT0	V41100 is the word memory reference for discrete bits T0 through T17, therefore, it's alias is VT0. V41101 is the word memory reference for discrete bits T20 through T37, therefore, its alias is VT20.
V41140	VCT0	V41140 is the word memory reference for discrete bits CT0 through CT17, therefore, it's alias is VCT0. V41141 is the word memory reference for discrete bits CT20 through CT37, therefore, its alias is VCT20.
V41200	VSP0	V41200 is the word memory reference for discrete bits SP0 through SP17, therefore, it's alias is VSP0. V41201 is the word memory reference for discrete bits SP20 through SP37, therefore, its alias is VSP20.

X Input / Y Output Bit Map

This table provides a listing of individual Input and Output points as associated with each V-memory address bit in the D4-454 CPUs.

MSB															D4-454 Input (X) and Output (Y) Points															LSB	
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	X Input Address	Y Output Address

Stage Control / Status Bit Map

This table provides a listing of individual stage control bits associated with each V-memory address bit.

MSB			Stage (S) Control Bits													LSB		Address
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0			
017	016	015	014	013	012	011	010	007	006	005	004	003	002	001	000	V41000		
037	036	035	034	033	032	031	030	027	026	025	024	023	022	021	020	V41001		
057	056	055	054	053	052	051	050	047	046	045	044	043	042	041	040	V41002		
077	076	075	074	073	072	071	070	067	066	065	064	063	062	061	060	V41003		
117	116	115	114	113	112	111	110	107	106	105	104	103	102	101	100	V41004		
137	136	135	134	133	132	131	130	127	126	125	124	123	122	121	120	V41005
